ABSTRACT

A field experiment was conducted at Zonal Agricultural Research Station, Visweswaraiah Canal Farm, Mandya (Karnataka) during Kharif seasons of 2011 and 2012 to study the response of multicut fodder sorghum to different seed rates and nitrogen levels under protective irrigated condition. The experiment consisted of 12 treatments, tested in randomized complete block design with factorial concept replicated three times. The pooled data indicated that seed rate of 7.5 kg/ha recorded significantly higher green fodder (74.10 t/ha), dry matter yield (17.41t/ha) and growth parameters like plant height (150.77 cm), number of tillers per meter row length (73.08), leaf stem ratio (0.25), net returns (Rs. 35018) and B: C ratio (2.40). Among nitrogen levels, application of 30 kg/ha recorded significantly higher green fodder (69.60 t/ha), dry matter yield (15.91 t/ha) and growth parameters like plant height (148.37 cm), number of tillers per meter row length (69.97), leaf stem ratio (0.23), crude protein yield (1.26 t/ha), crude fiber yield (5.34 t/ha), nitrate nitrogen content (1168.06 ppm), net returns (Rs. 31285/ha) and B: C ratio (2.20).

Key words: Green fodder, Crude protein, Crude fiber, Nitrate nitrogen

INTRODUCTION

Forages are the back bone of livestock industry. The mainstay of animal wealth and their production depends on availability of fodder. The scarcity of green forages and grazing resources in the country has made the livestock to suffer continuously with malnutrition resulting in their production

potentiality at sub optimum level as compared to many developed nations. India is having the largest livestock population of 520 million heads, which is about 15 per cent of the world's livestock population, supporting 55, 16, 20 and 4 per cent of world's buffaloes, cattle, goats and sheep population, respectively.

Cite this article: Somashekar, K.S., Shekara, B.G., Vidyashree, D.N., Lalitha, B.S. and Bhavya, V., Effect of Different Seed Rates and Nitrogen Levels on Growth, Yield, Quality and Economics of Multicut Fodder Sorghum (Sorghum sudanense L.), Int. J. Pure App. Biosci. 6(1): 1108-1115 (2018). doi: http://dx.doi.org/10.18782/2320-7051.3063

But, the country has only 4.4 per cent of the cultivated area under fodder crops with an annual total forage production of 833 million tons (390 m t green and 443 m t dry fodders). Whereas, the annual forage requirement is 1594 million tons (1025 m t green and 569 m t dry) to support the existing livestock population. The present feed and fodder resources of the country can meet only 48 per cent of the requirement, with a vast deficit of 52 per cent (61.1% and 21.9% of green and dry fodder)². The livestock breeds with higher milk yield potential are suffering from deficit of green and dry fodder availability in the country. To overcome this deficit, dairy farmers resort to the increased use of costly concentrate feeds, which increases the cost of production. The feed cost alone accounts for 65 to 70 per cent of the total cost of milk production. Keeping these things in view the present investigation was carried out for achieving maximum production, good quality and economics.

MATERIAL AND METHODS

A field experiment was conducted during Kharif seasons, 2011 and 2012 at Zonal Agricultural Research Station, Vishweswaraiah Canal Farm, Mandya (Karnataka) to assess the growth, yield and economics of multicut fodder sorghum as influenced by different seed rates and nitrogen levels. The soil of experimental field is red sandy loam with neutral soil pH (6.86), medium in available nitrogen (297.5 kg/ha), phosphorous (34.20 kg/ha) and potassium (34.20 kg/ha). The experiment was laid out in randomized complete block design with factorial concept with three replications. The experiment consisted of 12 treatment combinations viz., three levels of seed rates (5, 7.5 and 10 kg/ha¹ and four levels of nitrogen (15, 30, 45 and 60 kg N/ha for each cut). Equal quantity of farm yard manure at the rate of 10 t/ha was applied to each plot three weeks prior to sowing. The recommended dose of 40 kg of nitrogen, 50 kg P₂O₅ and 40 kg K₂O/ha was applied uniformly as basal dose at the time of sowing in the form of urea, single super

phosphate and muriate of potash, respectively. The remaining 45 kg of nitrogen was applied in two equal splits each at 30 DAS and 45 DAS in the form of urea for establishment of the crop. After the first cut the nitrogen was applied as per treatment for each cut. Fodder sorghum variety CoFS-29 was sown in line 30 cm apart. The crop was sown during last week of July and harvested when crop attained full flowering which is considered to be ideal stage for quality fodder. Five plants were randomly selected in each net plot area for taking observations on growth and yield attributing parameters. The crop in each net plot was harvested separately as per treatment and the values were converted in to hectare basis and expressed in tons. The samples were first dried under shade and then in electric oven at a temperature of 60° C till attain constant, weight on the basis of these samples, the green fodder yield was converted in to dry matter yield. The data of all four cuts is pooled and statistically analyzed for interpretation of results.

RESULTS AND DISCUSSION

Growth Parameters

Plant Height

Irrespective of N levels, significantly mean higher plant height was recorded with seed rate of 7.5 kg/ha (150.77 cm) as compared to that with seed rate of 5 kg/ha (146.88 cm) and was on par with seed rate of 10 kg/ha (138.89 cm). The higher plant height in seed rate of 7.5 kg/ha was mainly due to reduced competition within the intra row spacing as compared to higher seed rate. The findings of Singh et al¹⁴. (2005) confirmed the results. The plant height increased significantly with increase in level of nitrogen. Application of 60 kg N/ha for each cut recorded significantly higher plant height (157.13 cm) than 15 kg N/ha (132.89 cm) which was on par with 45 kg and 30 kg N/ha for each cut (151.41 cm and 148.37 cm, respectively). The higher plant height on higher levels of nitrogen is mainly attributed to more availability and uptake of nitrogen by crop which resulted in more vegetative growth and increase in protoplasmic constituent and acceleration in the process of cell division, expansion and differentiation and there by resulting in luxuriant growth. The findings of Agarwal et al^1 ., and Tiwana and Puri¹⁶ confirmed the results.

Leaf Stem Ratio

Seed rate of 7.5 kg/ha recorded significantly higher leaf: stem ratio (0.25) than seed rate of 5 kg/ha (0.22) and was on par with seed rate of 10 kg/ha (0.24) from the pooled mean. The higher leaf stem ratio with the seed rate of 7.5 kg/ha is due to increased leaf size and decreased stem girth. In higher seed rate because of more population per unit area leads to grassy shoot appearance. At lower seed rate more space is available for crop growth resulted in higher stem girth which leads lower leaf stem ratio in both higher and lower seed rate respectively. The similar kind of results was reported by Verma et al¹⁸. In pooled analysis, among the nitrogen levels application of 60 kg N/ha recorded significantly higher leaf stem ratio (0.26) as compared to that with 15 kg N/ha (0.21) and was on par with 45 kg and 30 kg N/ha (0.25 and 0.23). The increase in leaf stem ratio with increasing levels of nitrogen was mainly due to rapid expansion of dark green foliage which could intercept and utilize the incident solar radiation in the production of photosynthates and eventually resulting in higher meristematic activity and increased leaf stem ratio of fodder sorghum. This might be also due to favorable influence of nitrogen on cell division and cell elongation, which could have produced more functional leaves for a longer period of time. These results are in conformity with the findings of Singh and Gill¹³, and Gardner Franklin *et al*⁶.

Number of Tillers Per Meter Row Length

Tillers per meter row length increased significantly with increase in seed rate. Irrespective of N levels significantly mean higher number of tillers per meter row length was obtained with the seed rate of 7.5 kg/ha (73.08) as compared to that with seed rate of 5 kg/ha (61.84) and was on par with seed rate of 10 kg/ha (67.56). This is mainly attributed to lesser competition for space within the plant

row due to moderate plant population resulted in better root growth and expansion which leads to profuse tillering in seed rate of 7.5 kg/ha. In higher seed rate of 10 kg/ha more number of tillers is obtained per meter row length in the first cut but later on due to more competition for space the mortality of tillers was noticed which resulted in lower number of tillers in subsequent cut. The results are in conformity with the findings of Verma et al¹⁸. In pooled analysis, application of 60 kg N/ha for each cut recorded significantly higher number of tillers per meter row length (76.05) than 15 kg N/ha (60.98) and was on par with 45 kg and 30 kg N/ha (73.51 and 69.97 respectively). This was mainly due to increased vegetative growth and capacity to produce more number of tillers under higher nitrogen levels. These results are in conformity with the findings of Chaurasia et al^4 .

Yield Parameters

Green Fodder Yield

Green fodder yield significantly was influenced by seed rates and nitrogen levels. Pooled data indicated that seed rate of 7.5 kg/ha recorded significantly higher green fodder yield (74.10 t/ha) as compared to that with seed rate of 5 kg/ha (60.99 t/ha) and was on par with seed rate of 10 kg/ha (69.28 t/ha). The higher green fodder yield in seed rate of 7.5 kg/ha was mainly due to higher plant height, number of tillers per meter row length, and leaf stem ratio. Apart from this the over burden of the plant population which might compete for light and nutrients which leads to lanky growth and grassy shoot appearance resulted in lower green fodder yield in seed rate of 10 kg/ha. These results are in conformity with the findings of Mishra et al⁹., Gaurkar and Bharad⁷, Naganagouda¹⁰. Among nitrogen levels, application of 30 kg N/ha recoded significantly higher green fodder yield (69.60 t/ha) as compared to that with 15 kg N/ha (57.84 t/ha) and was on par with 45 and 60 kg N/ha (70.80 and 73.80 t/ha) on pooled data basis. This may be mainly attributed to improved growth and yield parameters, viz., plant height, number of tillers per meter row,

ISSN: 2320 - 7051

leaf stem ratio and the beneficial effects of nitrogen on cell division and elongation, formation of nucleotides and Co-enzymes which resulted in increased meristematic activity and photosynthetic area and hence more production and accumulation of photosynthates, yielding higher green fodder and dry matter. These results are in conformity with the findings of, Dudhat *et al*⁵., Sharma and Verma¹¹, Sheoran and Rana¹². The similar trend was observed in both the years.

Dry Matter Yield

Dry matter yield was significantly influenced by seed rates and nitrogen levels. Pooled data indicated that seed rate of 7.5 kg/ha recorded significantly higher dry matter yield (17.41 t/ha) as compared to that with seed rate of 5 kg/ha (13.37 t/ha) and was on par with seed rate of 10 kg/ha (16.64 t/ha). Among nitrogen levels, application of 30 kg N ha⁻¹ recoded significantly higher dry matter yield (15.91 t/ha) as compared to that with 15 kg N/ha (12.89 t/ha) and was on par with 45 and 60 kg N/ha (16.15 and 17.11 t/ha, respectively) on pooled data basis.

Quality Parameters

Crude Protein Yield (t/ha)

The crude protein yield of multicut fodder sorghum differed significantly due to seed rates and nitrogen levels. Seed rate of 7.5 kg/ha recorded significantly higher total crude protein yield (1.40 t/ha) as compared to that with seed rate of 5 kg/ha (1.02 t/ha) and was on par with seed rate of 10 kg/ha (1.31 t/ha). This was probably due to higher dry matter production and partition. These results confirmed the findings of Bishnol et al³. The crude protein yield increased significantly with increase in level of nitrogen. In pooled analysis, application of 60 kg N/ha for each cut recorded significantly higher total crude protein yield (1.42 t/ha) than 15 kg N/ha (0.89 t ha⁻¹) and was on par with 45 kg and 30 kg N/ha for each cut (1.30 t and 1.26 t/ha, respectively). This is due to higher crude protein content and dry matter yield with higher levels of nitrogen. This is in conformity with the findings of Gupta et al^8 .

Crude Fiber Yield (t/ha)

Crude fiber yield of multicut fodder sorghum differed significantly due to seed rates and nitrogen levels. In pooled analysis seed rate of 7.5 kg/ha recorded significantly higher total crude fiber yield (6.11 t/ha) as compared to that with seed rate of 5 kg/ha (4.75 t/ha) and was on par with seed rate of 10 kg/ha (5.45 t/ha). This was probably due to higher dry matter production and partition. Among nitrogen levels, application of 60 kg N/ha for each cut recorded significantly higher total crude fiber yield (5.64 t/ha) than 15 kg N/ha for each cut (4.53 t/ha) and was on par with 45 kg and 30 kg N/ha for each cut (5.47 t and 5.34 t/ha respectively). The higher total crude fiber yield with higher nitrogen level of 60 kg N/ha was mainly due to significant increase in dry matter yield with increased N levels. These results confirmed the findings of Bishnol et al^3 .

Nitrate Nitrogen Content (ppm)

Nitrate nitrogen content of multicut fodder sorghum did not differed significantly due to seed rates. In pooled analysis the mean higher Nitrate-nitrogen concentration was recorded with seed rate of 5 kg/ha and lower with seed rate of 7.5 kg/ha (1247.15 and 1287.80 ppm, respectively). In pooled analysis application of 60 kg N/ha for each cut recorded significantly higher nitrate-nitrogen concentration (1502.63 ppm) which was significantly superior over other levels of Nitrogen (1066.54 to 1288.28 ppm respectively). This was mainly due to more uptake of nitrogen with increasing level of nitrogen which leads to more accumulation of nitrogen in plants. These results are in conformity with the findings of Vasanthi and Kumarswamy¹⁷ and Tiwana et al¹⁵.

Economics

Higher gross returns (Rs. 59911/ha), net returns (Rs. 35018/ha) and B: C ratio (2.40) was obtained with the seed rate of 7.5 kg/ha as compared to that with seed rate of 10 kg/ha and 5 kg/ha. This was mainly due to higher green forage yield and less cost of production as compared to 5 kg and 10 kg seeds per hectare. Among nitrogen levels, significantly higher gross returns (Rs. 59987/ha) and net

returns (Rs. 32550/ha) were obtained with 60 kg N/ha which was on par with application of 30 kg N/ha for each cut (Rs. 57350/ha, Rs. 31285/ha, respectively). However, significantly higher B: C ratio was obtained

with 30 kg N/ha for each cut (2.20). This is due to higher green fodder yield with minimum incremental nitrogen level and lower cost of cultivation.

CONCLUSION

Based on the result it can be inferred that seed rate of 7.5 kg/ha with 30 kg N/ha for each cut found optimum and economical which recorded higher growth, yield, quality, net returns and B:C ratio.
